# Data Assimilation for Reanalysis

Dick Dee

Massimo Bonavita, Mike Fisher, Paul Poli, David Tan

**ECMWF**

WCRP 4<sup>th</sup> International Conference on Reanalyses

7-11 May 2012

Silver Spring, Maryland

# Reanalysis of the instrumental record

## Special challenges for data assimilation:

- Maintaining temporal consistency
- Time-varying background errors
- Using sparse observations
- Uncertainty estimates
- Computational cost

## Topics for this talk:

- Ensemble Data Assimilation
- Long-window 4D-Var
- Use of weak-constraint 4D-Var to control model biases

## Some advantages as well:

- Knowledge of the complete data record
- No strict real-time requirement
- Iteration (we have a second chance)

# Approach taken in ERA-CLIM

---

Develop a 20<sup>th</sup>-century climate reanalysis from the bottom up:

- Model + boundary conditions, atmospheric forcing data
- Reanalysis of surface observations only
- Reanalysis of early upper-air observations
- Reanalysis of reprocessed satellite data

Beyond ERA-CLIM:

- Comprehensive 20C atmospheric reanalysis
- Some form of coupling with the ocean
- Should begin production by end of 2014

This is a long-term project!

# Choice of data assimilation method

---

ECMWF systems are based on 4D-Var analysis

- Has been successfully used in ERA-Interim
- Variational bias correction is important for reanalysis
- Options: longer analysis window, accounting for model errors

Major shortcoming: Background errors are not dynamic

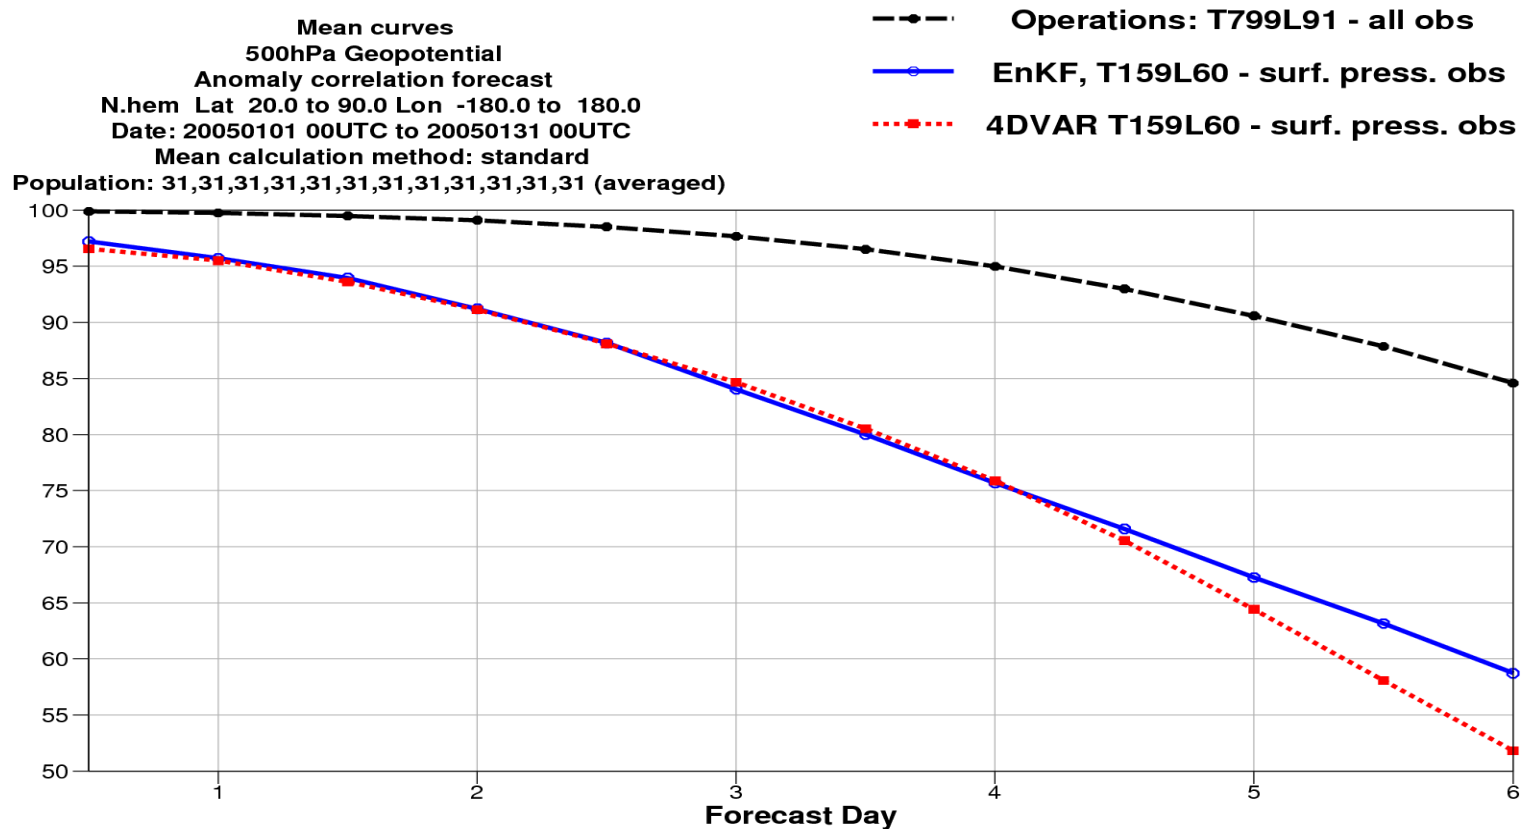

- Uses a stationary covariance model
- Flow-dependence induced by balance operators
- Manually tuned (model-dependent)

What about an ensemble Kalman filter (EnKF)?

- Implemented at ECMWF in collaboration with Jeff Whitaker

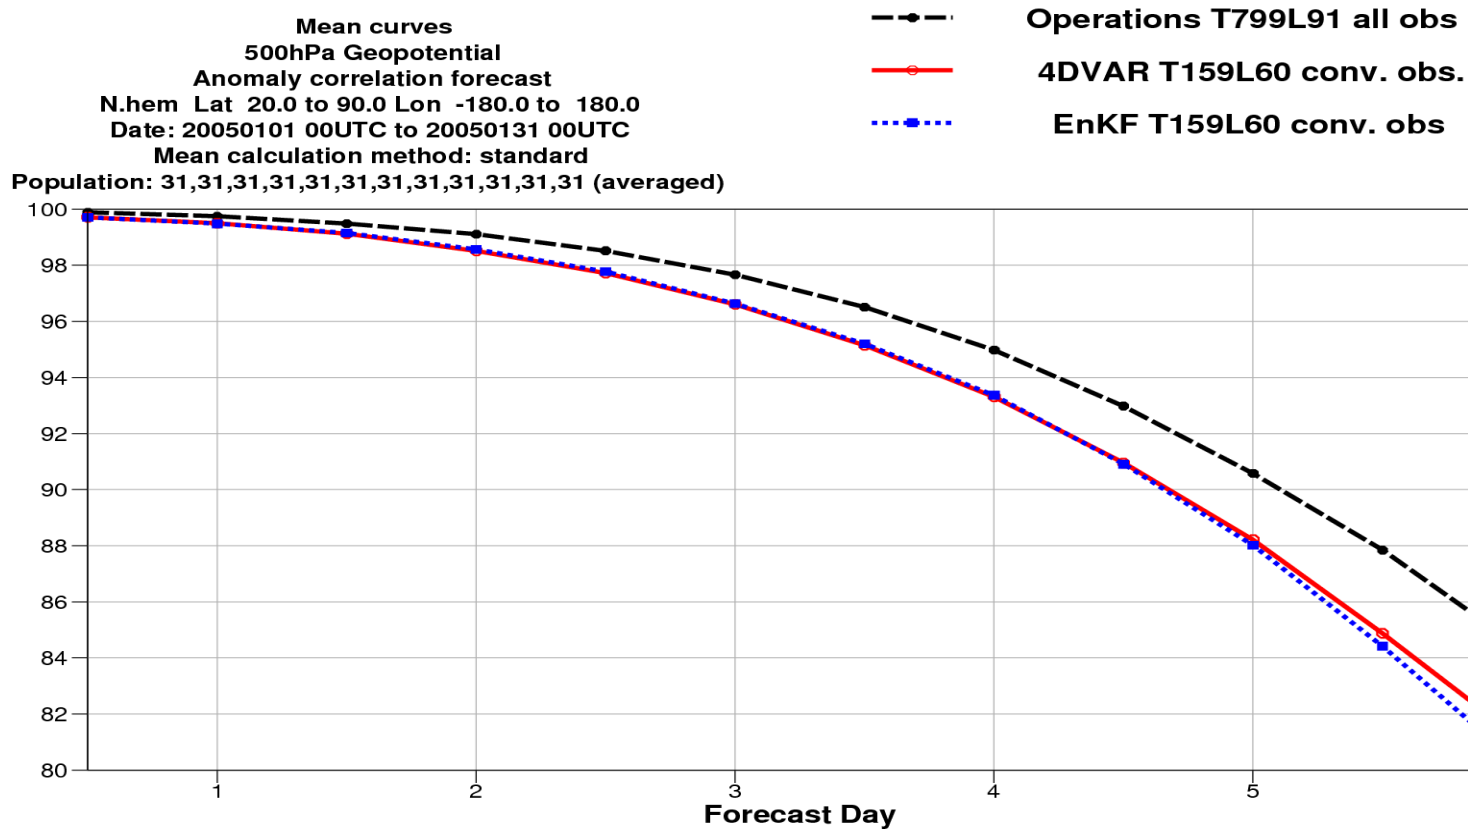

# EnKF vs 4D-Var experiments

## Assimilating surface pressure observations only

# EnKF vs 4D-Var experiments

## Assimilating all conventional observations

# EnKF vs 4D-Var experiments

## Assimilating all conventional and satellite observations

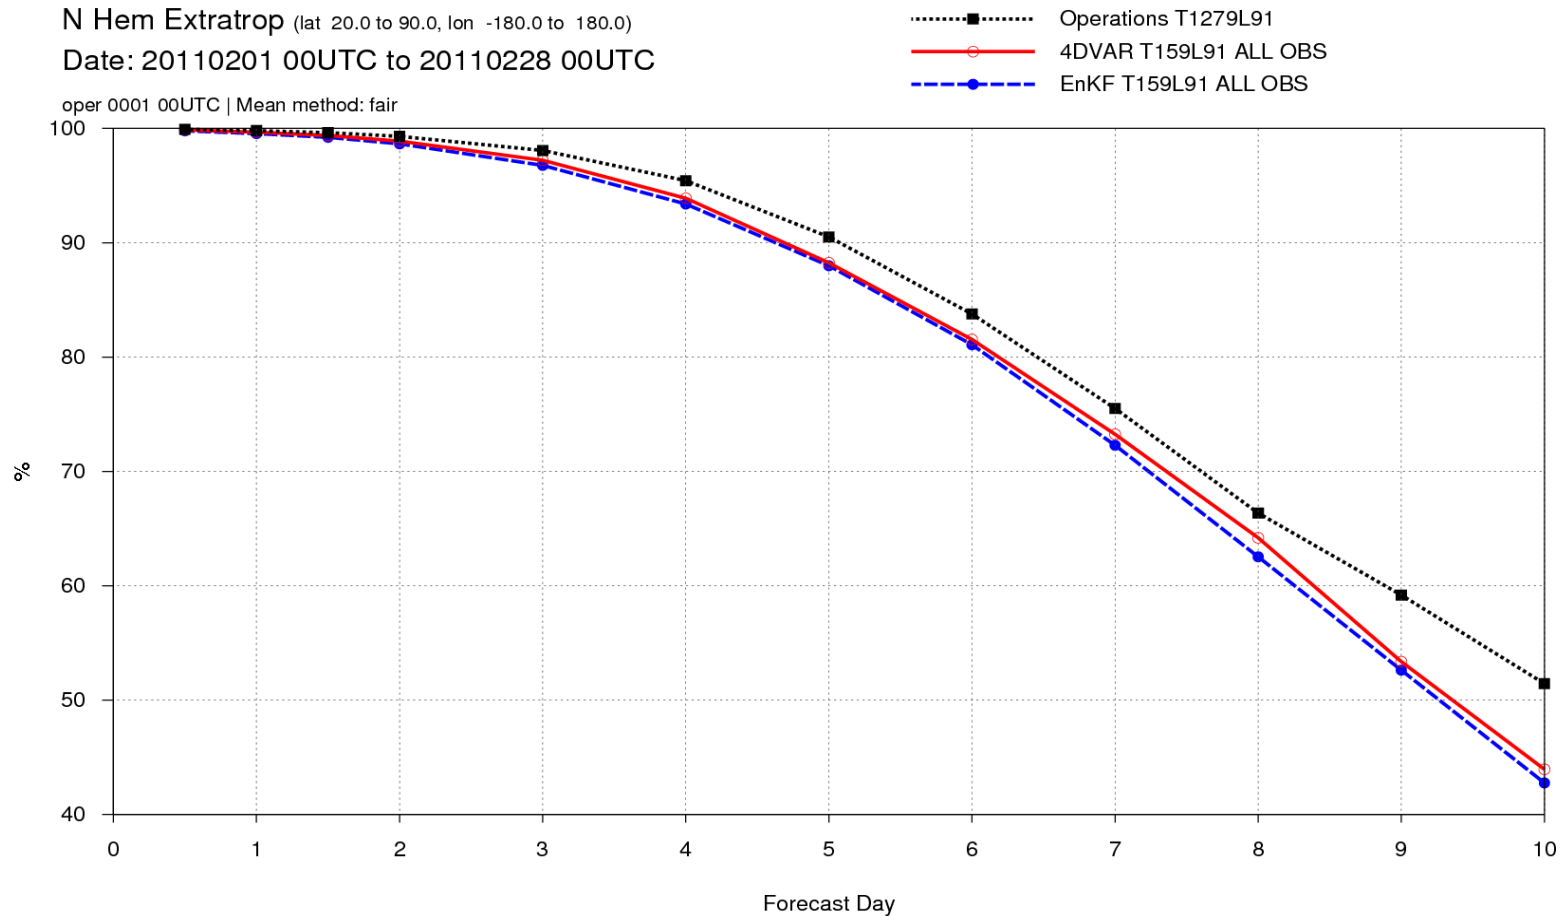

500hPa geopotential

Correlation coefficient of forecast anomaly

N Hem Extratrop (lat 20.0 to 90.0, lon -180.0 to 180.0)

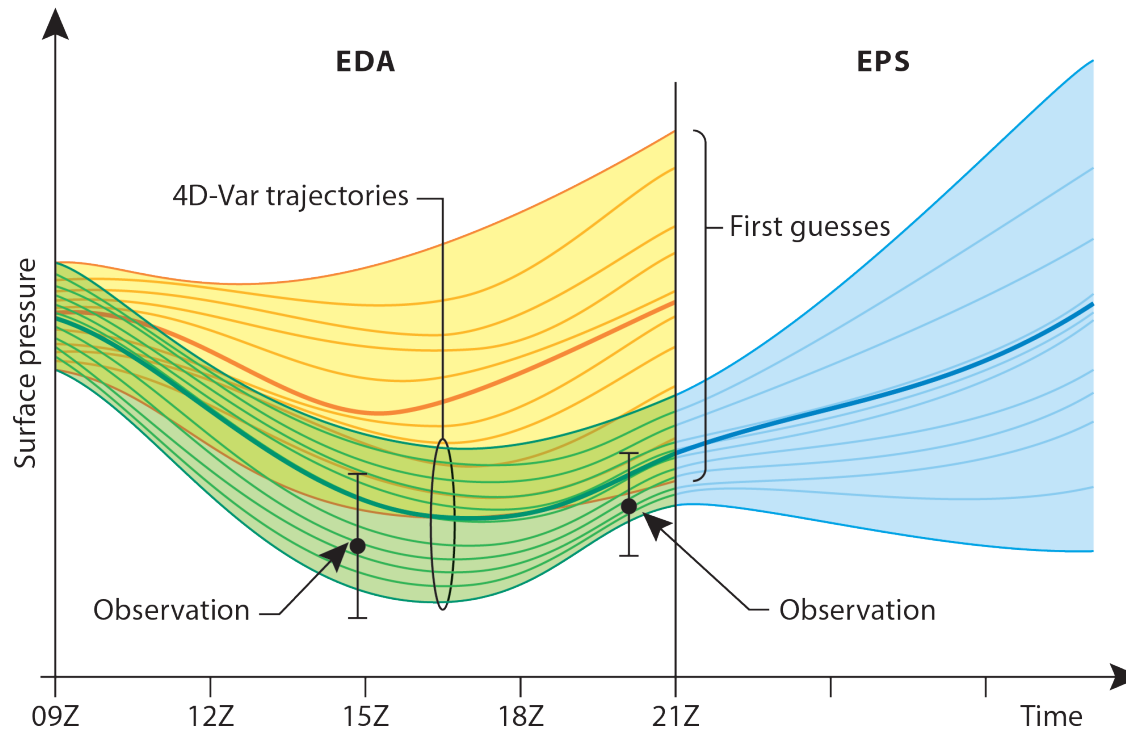

Date: 20110201 00UTC to 20110228 00UTC

oper 0001 00UTC | Mean method: fair

# Development of a hybrid EDA/EnKF

An ensemble of low-resolution (T399) 4D-Var data assimilations (EDA) is now used to estimate analysis and background errors for the operational forecasting system (T1279)

The EDA also creates perturbations for the ensemble prediction system (EPS)

# Flow-dependent background errors

Hurricane Fanele  
Indian Ocean, January 2009

# EDA with 20 members

Surface pressure error standard deviation [hPa]

Correlation length scales

[km]

Variance estimates are fully flow-dependent; correlations not yet

# EDA configuration for ERA-20C

Ensemble of reanalyses from 1900, surface observations only, T159/L91/N10

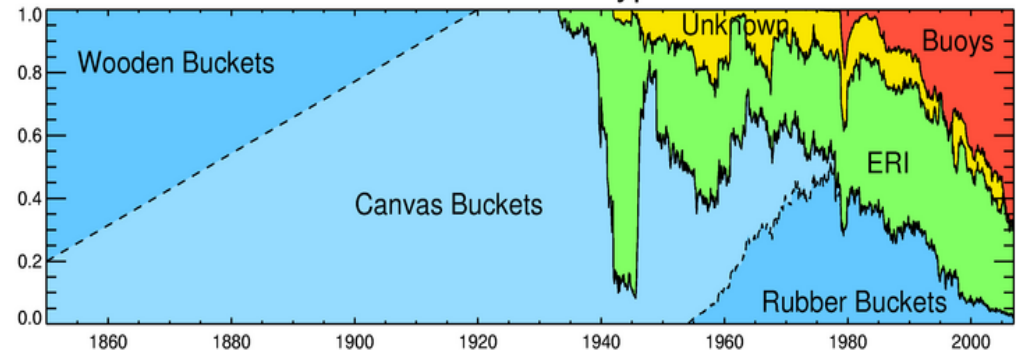

10 members defined by:

- Different HadISST2 realizations
- Stochastic physics in the forecast model
- Randomly perturbed observations

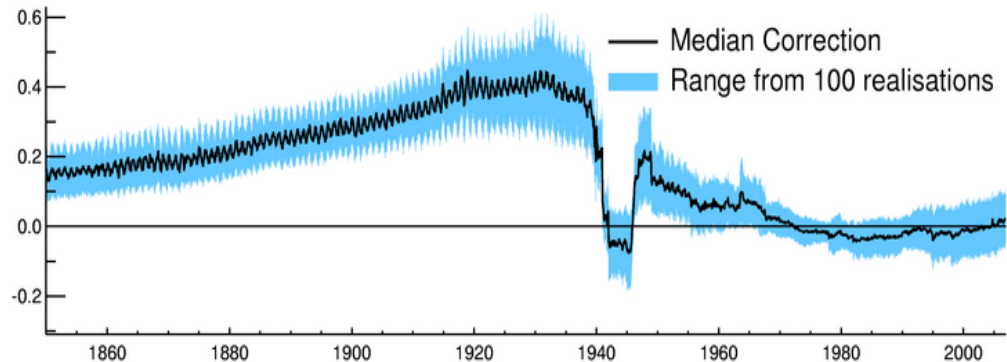

Background error variances estimated from ensemble

Still relying on stationary correlation structures

Fraction of Measurements from each Type in ICOADS

Bias corrections used in HadISST2

# Long-window 4D-Var

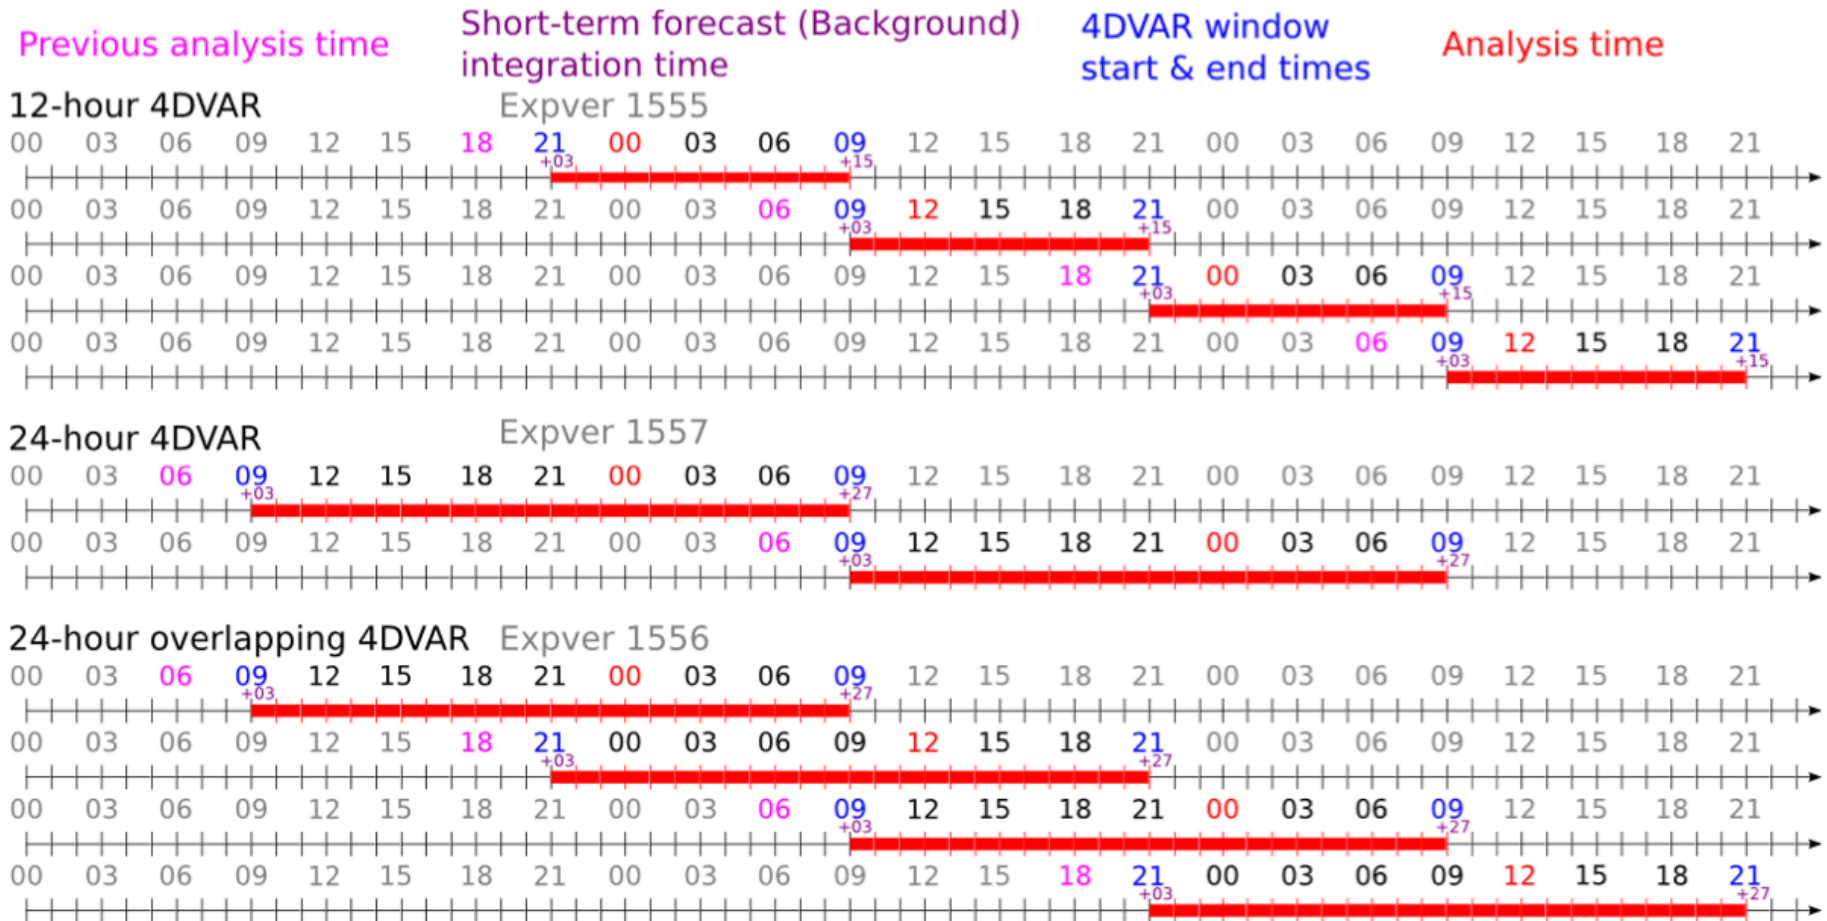

Experiments with a 2-level QG model with realistic model errors

- Longer windows  $\rightarrow$  smaller background errors
- Analysis errors are smallest in the interior of the window
- This is easier to exploit in reanalysis than in forecasting

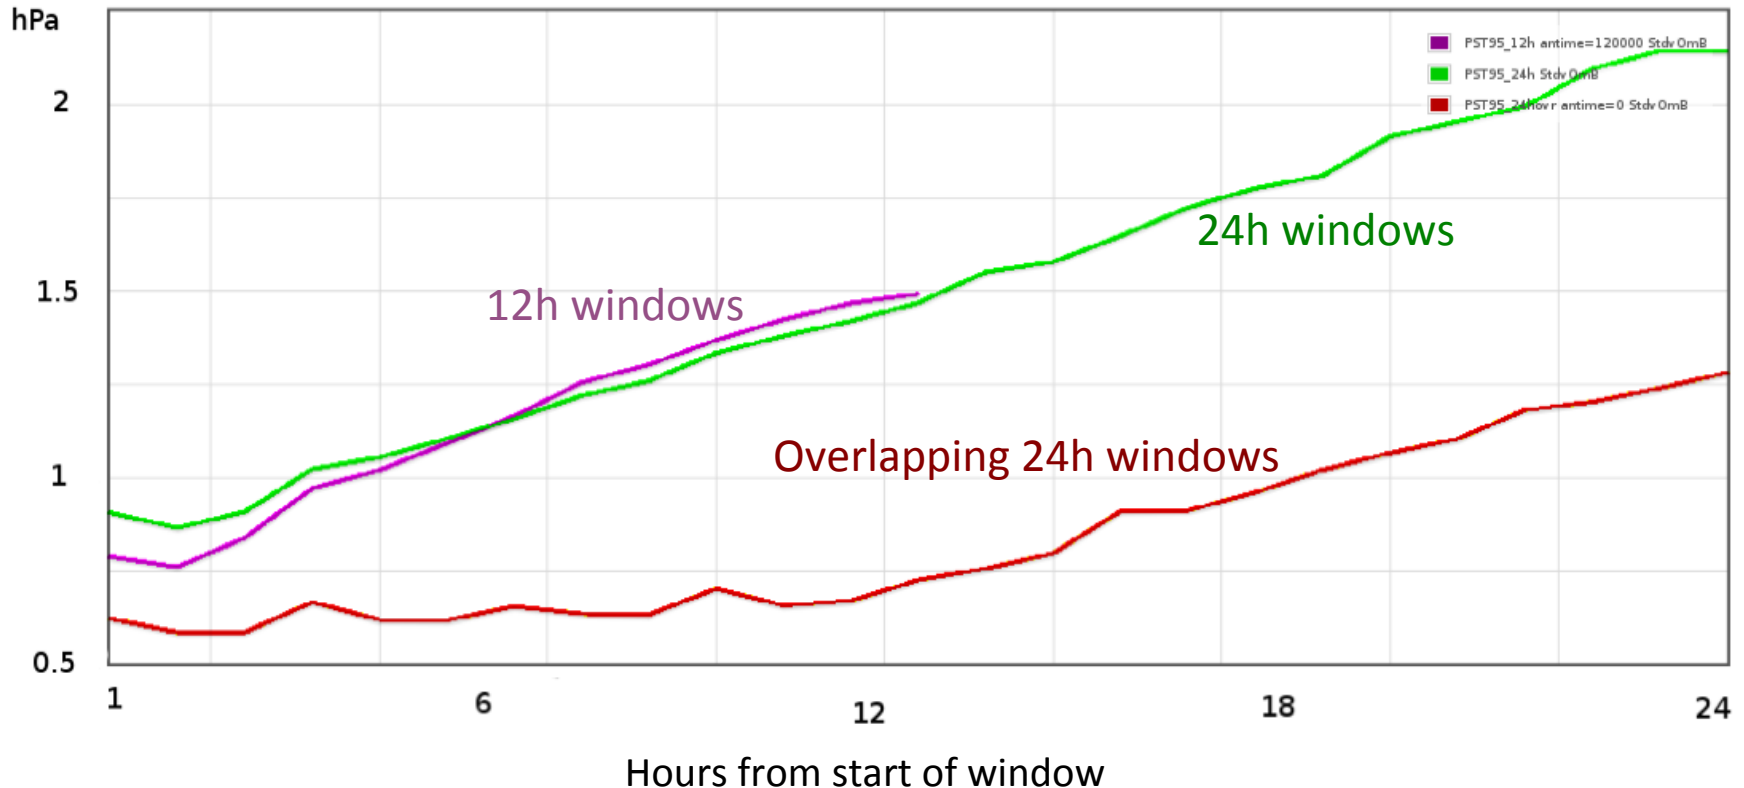

# Cycling schemes

Overlap is necessary for even longer windows, to get an accurate first guess

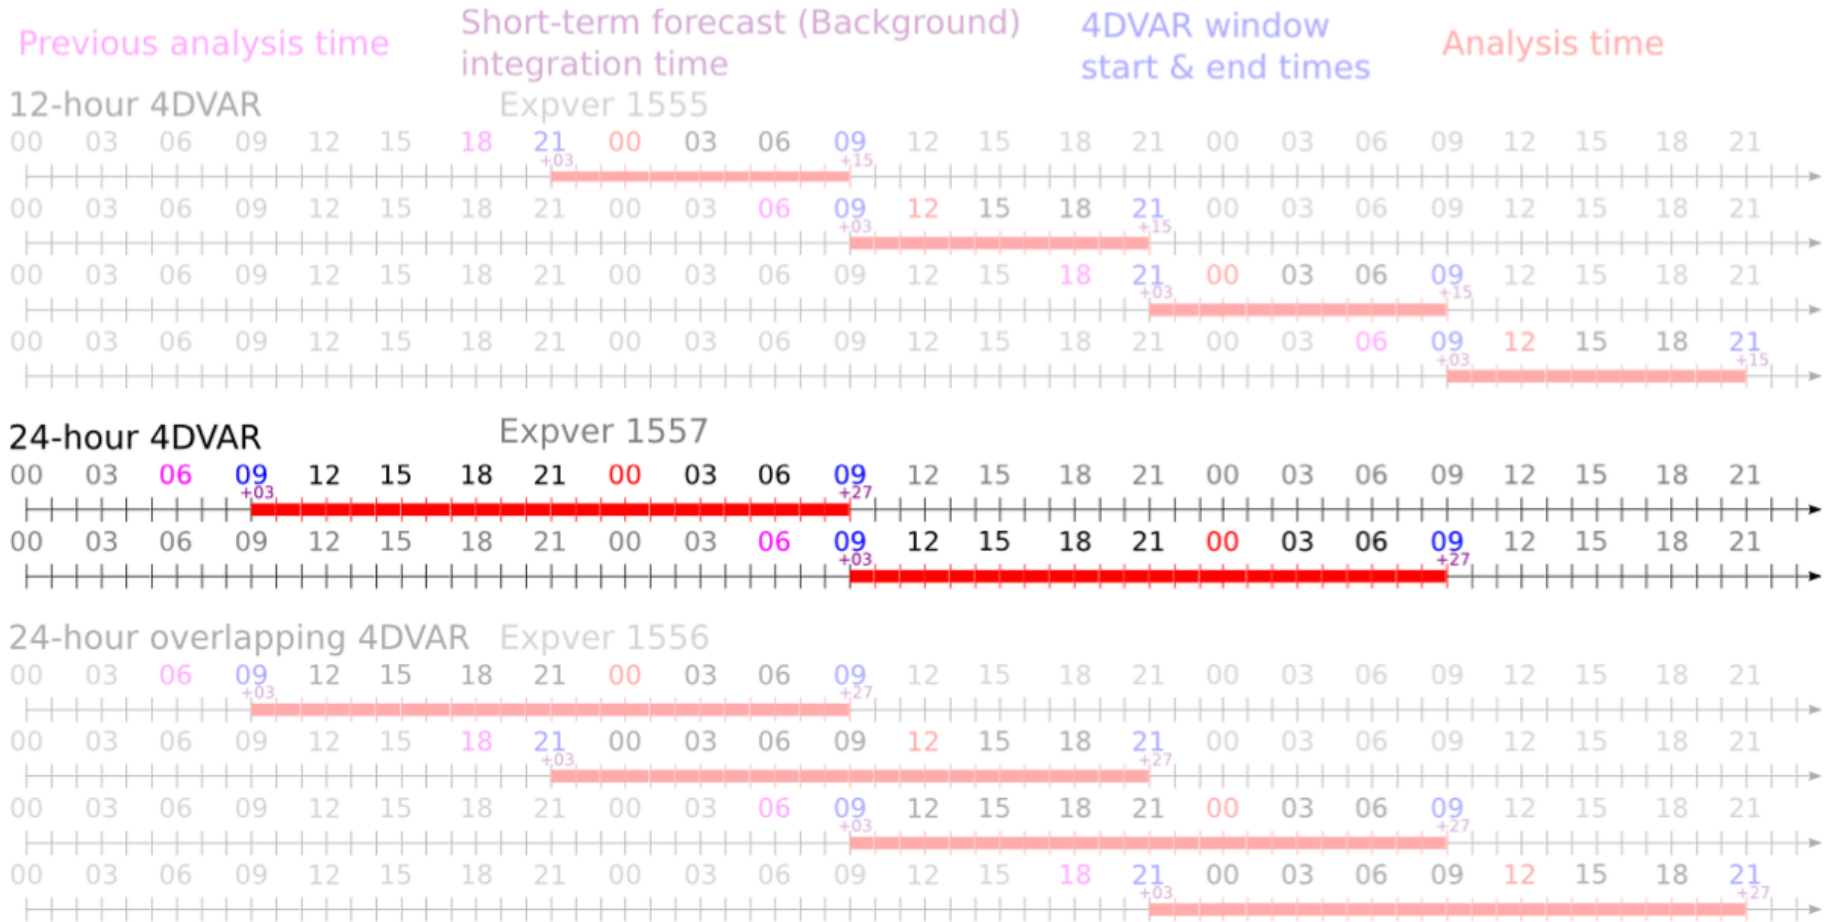

# Assimilating surface pressure only

Background forecasts verified against surface pressure observations

Overlapping 24h windows is much better – but too expensive for ERA-20C

# ERA-20C will use 24h 4D-Var

# Weak-constraint 4D-Var

Implementation of long-window 4D-Var requires the addition of model error terms in the variational analysis equation:

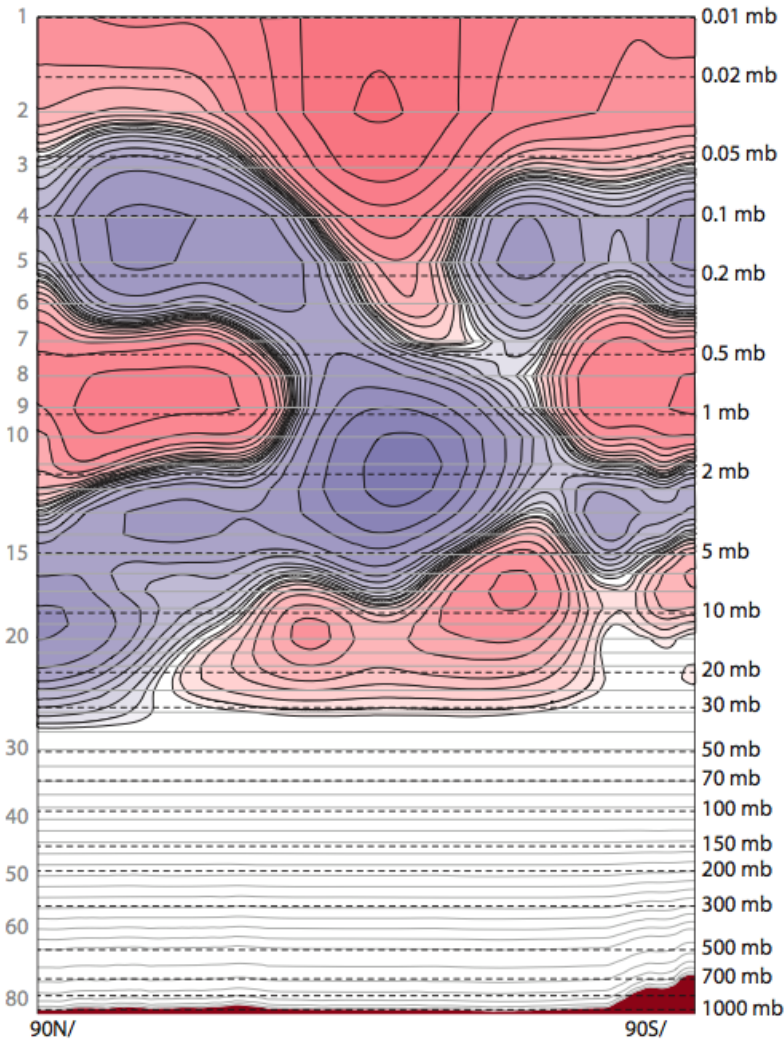

Weak-constraint 4D-Var can also be used to estimate persistent model errors.

# Model bias estimates from weak-constraint 4D-Var

Estimated persistent model error [K/12h]

10-day minus 5-day forecast drift [K/day]

# Controlling model bias in reanalysis

---

Can we use model error estimates from weak-constraint 4D-Var to control the effect of model bias in the absence of observations?

- For a given model, estimate persistent model errors in the recent (well-observed) period
- Apply these as a correction to the model in the past (poorly-observed) period

A similar approach has been successfully applied in ECMWF's ocean reanalysis (*Magdalena Balmaseda*).

Experiment:

- Estimate persistent stratospheric model error in a fully observed system, using weak-constraint 4D-Var
- Apply the estimate to correct the model in an assimilation of surface pressure observations only

# Mean forecast errors, T at 10hPa

Mean curves, 10 hPa temperature. Mean error forecast. N. Hemisphere  
Date: 20100301 00 UTC to 20100331 00 UTC. Mean calculation method: fair  
Population: 31,31,31,31,31,31,31,31,31,31

--- Control, uncycled model error, all obs      — Control, uncycled model error, ps only  
— Cycled d10-d5 covar, alphaq 0.05, all obs      — Cycled bgmoderr from 1551, ps only

# Summary

---

- ERA-CLIM uses the ECMWF Integrated Forecast System (IFS):
  - Ensemble of data assimilations (EDA)
  - Long-window weak-constraints 4D-Var
  - Variational bias correction of observations
- For climate reanalysis:
  - Use prior knowledge of the full data record for QC and bias correction
  - Use the ensemble to represent key uncertainties (SST/sea-ice)
  - Configure the analysis window to make best use of sparse observations
  - Use weak-constraints 4D-Var to estimate and correct model biases
- Coupling the ocean
  - CFSR is the starting point
  - Focus on controlling model drift with SST observations

# Need for a coupled system

Representation of the MJO in seasonal forecasting  
(E. de Boisseson and M. Almaseda)

- Coupling does better than forcing monthly SST. Alternative before 1981 ?
